

Session Initiation Protocol

- SIP is a signaling protocol standardized by the IETF; it is used together with other protocols such as Session Description Protocol (SDP), Real Time Streaming Protocol (RTSP) and Session Announcement Protocol (SAP)
- SIP handles the setup, tear down e management of IP multimedia sessions
- SIP usually adopts RTP as a transport for media streams
- SIP signaling has a dedicated logical channel, different from the logical channels used for the transport of media on the user plane

SIP entities

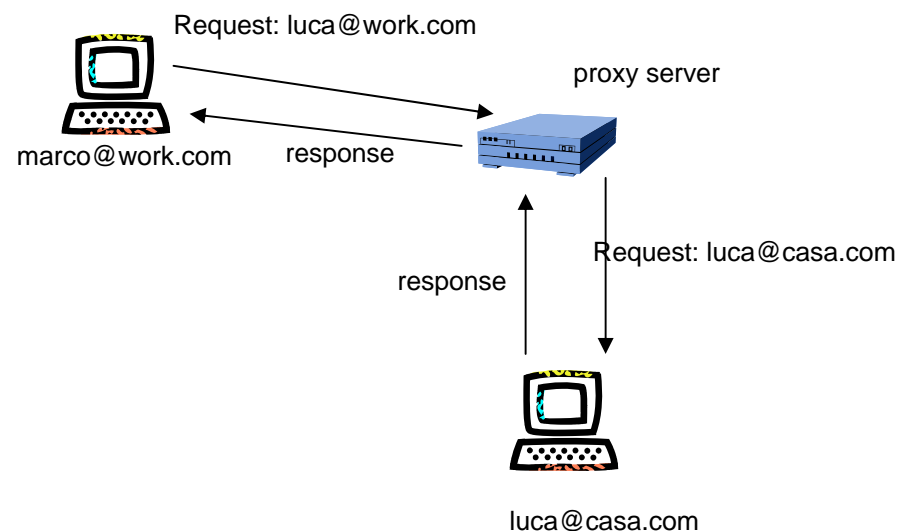

- SIP defines two types of entity:
 - client
 - Called also *user agent client*, it is an applications sending SIP requests
 - servers
 - Applications committed to the establishment of connections; servers respond to SIP requests from clients
- A SIP call involves at least two remote entities
 - user agent client
 - user agent server

SIP entities

- A SIP device can host both user agent client and server, this is the typical case of a user's device
- There are four basic types of SIP server
 - proxy server
 - redirect server
 - registrar server
 - user agent server
- A physical device can host multiple servers

Proxy (redirect) server

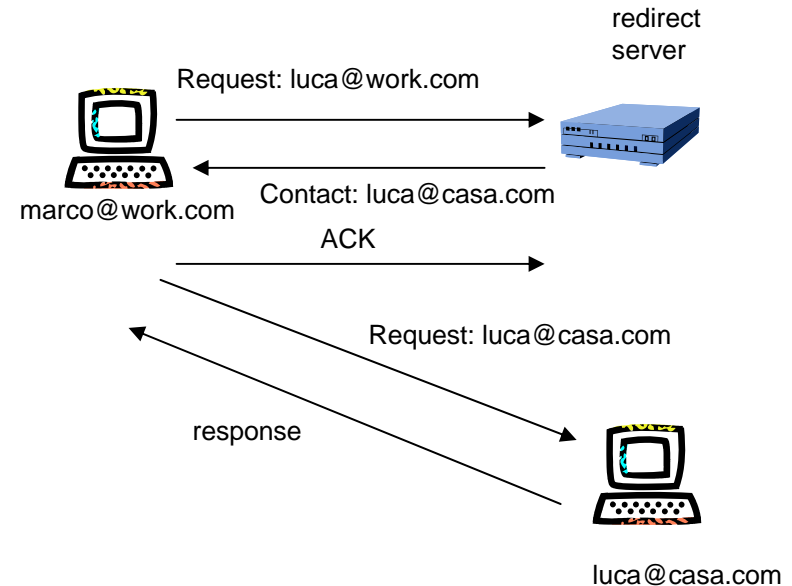

- A proxy server can implement multiple types of SIP server
- It can colloquiate both with user devices and other SIP servers in the network
- Through proxy servers it is possible to implement many value-added services such as
 - call forwarding
 - time-of-day routing

The example shows a simple use case of redirect service. Luca is at home and Marco calls him at work. The proxy redirects the call to the current Luca's location

Proxy (redirect) server

- The redirect server can also provide the calling terminal with an alternative address to call, instead of redirecting the call automatically

SIP applications (example)

- Find-Me-Follow-Me:
 - By using a web interface, a user can specify where calls should be forwarded to him, also in a time-dependent fashion
 - The user can ask the system to ring concurrently multiple terminals, or to scan a list of terminals sequentially
- With IVR (interactive voice response):
 - incoming calls can be redirected to an automatic responder
- Click-to-Dial:
 - It is a web browser-based application by which SIP calls are triggered by clicking an hyperlink in a web page
- Contact Manager
 - Access to a centralized contact list, from any user terminal and independently on the current geographic location of the user

User agent server

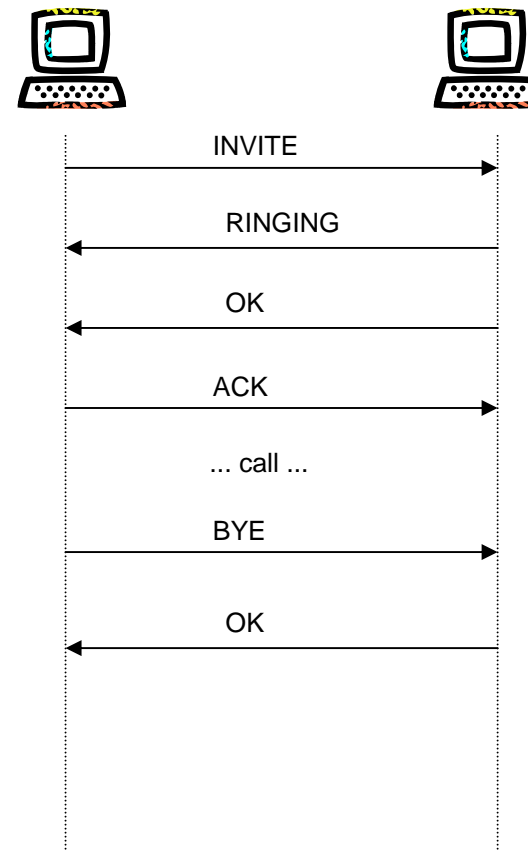

- It is the server usually installed on user terminals
- User terminals host also the user agent client
- The client is used to send signaling requests
- The user agent server receives incoming requests and responds

Registrar server

- The registrar server handles SIP REGISTER requests
- SIP REGISTER requests are used by devices to register into the SIP network
- After a successful registration, a SIP device is operative

SIP base call without proxy

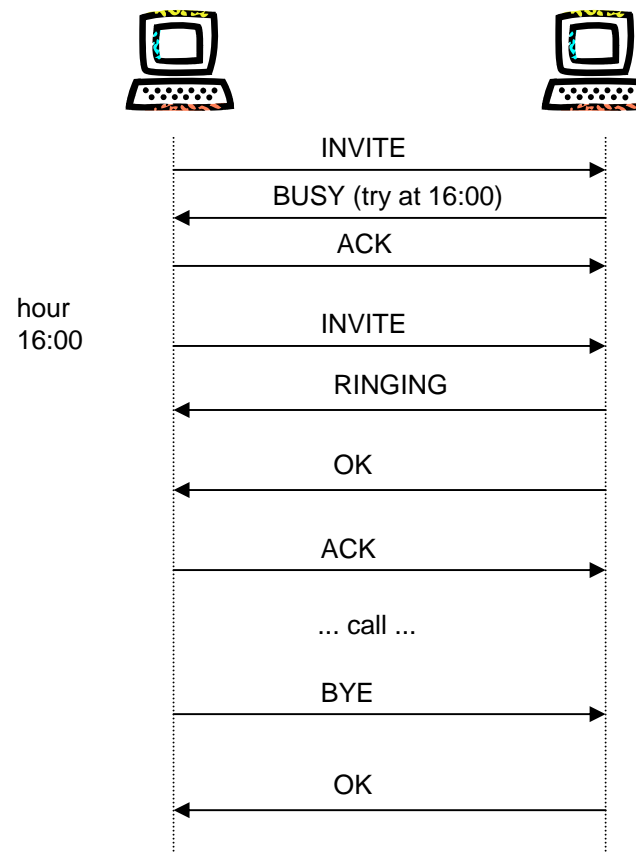

- The INVITE message is used to start a call
- In the simplest case shown in the figure, the user agent client sends the INVITE directly to the called device
- The remote user server sends a RINGING message to let the calling device know that the called terminal is ringing
- When the call is accepted at the called end, the OK message is sent
- The call is teared down with the BYE/OK pair of messages

SIP features

Caratteristiche di SIP

- SIP is a simple and flexible signaling protocol
- The parameters for media negotiation are carried in the body of SIP messages
- The figure shows an example of deferred call

SIP messages

- SIP messages can be either requests or responses
- SIP messages are in textual format
- In this way, it is simpler to analyze the behavior of signaling just parsing exchanges IP packets
- This is an advantage over binary signaling protocols
- However, textual messages usually consumes more bandwidth than binary protocols

```
message = start-line
         *message header
         CRLF
         [message-body]
```

```
start-line = request-line || status-line
```

SIP messages

- The request-line specifies the type of request and its parameters
- The status line specifies the type of response and its parameters
- The message-header carries information such as source and destination identification

```
message = start-line
         *message header
         CRLF
         [message-body]
```

```
start-line = request-line || status-line
```

SIP messages

- The message-body carries information such as
 - type of session
 - format of media
 - altra caratterizzazione
- SIP does not standardize the message body; in the case of media format information, the structure of the message body is standardized by the Session Description Protocol (SDP)
- The message body can also carry messages of other signaling systems: this is useful for signaling interworking

```
message = start-line
         *message header
         CRLF
         [message-body]
```

```
start-line = request-line || status-line
```

SIP requests

- SIP requests start with the request-line, consisting of blank-separated tokens:

- method
 - Type of requests
- Request-URI
 - Destination address of the request
- SIP-Version

- Basic methods are (RFC 3261)

- INVITE
- ACK
- OPTIONS
- BYE
- CANCEL
- REGISTER

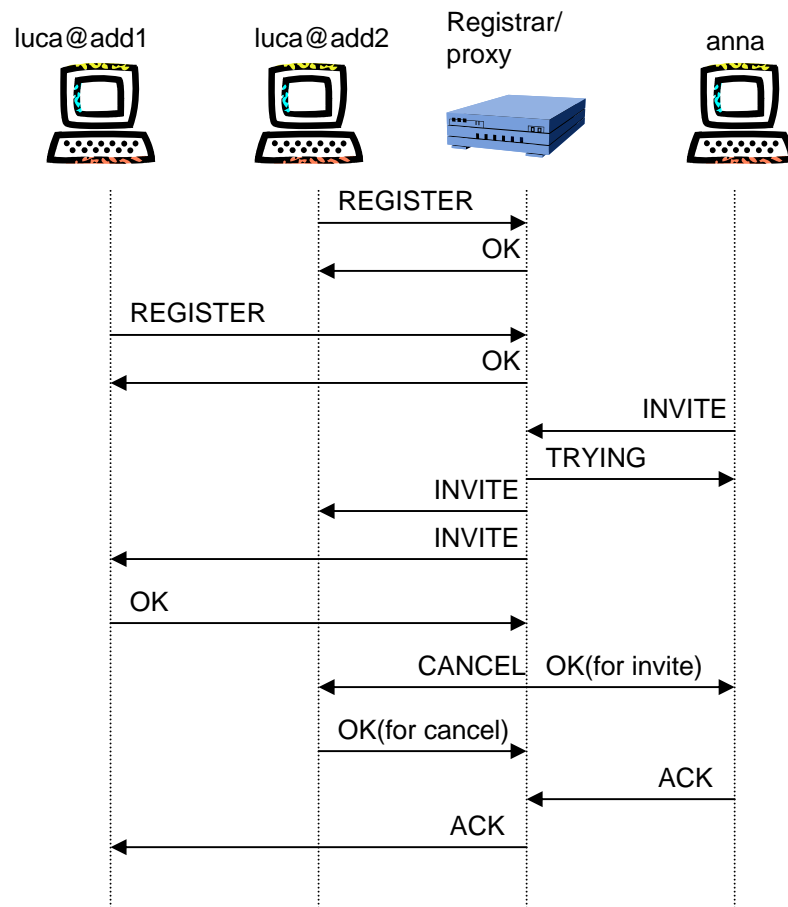

```
request-line = method SP Request-URI SP SIP-  
Version CRLF
```

SIP requests

- INVITE
 - To establish a call; it specified involved users and also the format of media
- ACK
 - Messages are usually ACKed; the ACK message must refer explicitly to the message it acknowledges
- BYE
 - To close a call
- CANCEL
 - To terminate an ongoing transaction
- REGISTER
 - Used to register a device

Example: one-number

- Luca is registered with multiple SIP addresses
- Anna calls Luca: the call is forwarded to all active registrations of Luca
- When one of the called terminal responds, the call is started

Additional methods

- The INFO method is useful to transmit information when a call is already active
- For example, this can be used to transport multifrequency tones

SIP response

- The status code is a three-digit number specifying the type of message
- The reason-phrase is a text field carrying additional information, depending of the type of message
- Status codes range from 100 to 699
- The first digit indicates the category of the response
 - 1xx: provisional (eg: 181 call forwarded)
 - 2xx: success (eg 200)
 - 3XX: redirect (eg, 302: retry calling the address specified in the reason phrase)
 - 4XX: failure
 - 5XX: Server failure
 - 6XX: Global failure (eg: called user does not exist)

```
status-line = SIP version SP status code SP  
              reason-phrase CRLF
```

**NOTE: all responses, with the exception of the 1XX
Provisional responses, must be ACKed**

SIP response

- Provisional
 - 100 trying
 - 180 ringing
 - 181 call forwarded
 - 182 call queued
 - 183 session in progress
- Success
 - 200 OK
- Redirection
 - 301 user moved permanently
 - 302 user mover temporarily
- Request failure
 - 400 bad request
 - 401 user not authorized
 - 415 unsupported media
 - 486 busy
- Server failure
 - 500 server internal error
- Global failure
 - 604 does not exist anywhere

```
status-line = SIP version SP status code SP  
              reason-phrase CRLF
```

SIP addressing

- SIP addresses are URIs (Uniform Resource Indicator)
 - SIP URI: sip:luca@home.milano.it

Message headers

- There are multiple header types
- To e From headers identify called and calling users
- Header can be:
 - general header
 - request header
 - response header
 - entity header

Message headers

- General header
 - They are used for both requests and response, e.g.: To, From ,Call ID ...
 - The Contact header is used for the redirection of calls
- Request Header
 - Used only for requests
- Response Header
 - Used only for responses

Message headers

- Entity Header
 - The main purpose of the entity header is to describe the content of the message body
 - Frequently used fields are
 - Content-length (*content length in bytes*)
 - Content-type (e.g. *application/SDP*)
 - Content-encoding
 - Content-disposition
 - To specify, for example, if the contents of the body must be displayed for the user
 - Content-language

Registration example

- Via header
 - The Via header specifies the SIP route followed by the message
 - The branch parameter is used to identify univocally the message, if proxies are used
- From header
 - Specifies the URI of the requesting entity
 - The tag field is used to help identifying univocally the user and user's transaction
- To: header
 - In this case, the To header coincides with the From header: this is to specify that Anna is registering herself

anna@pippo.lavoro.it

registrar

```
REGISTER sip:registrar.lavoro.it SIP/2.0
Via: SIP/2.0/UDP pippo.lavoro.it; branch = h739fhry
Max-Forwards: 70
From: sip:anna@pippo.lavoro.it; tag = 123456
To: sip:anna@pippo.lavoro.it
CALL-ID: 123456@pippo.lavoro.it
CSeq: 1 REGISTER
Contact: sip:anna@pippo.lavoro.it
Expires: 7200
Content-Length: 0
```

Registration example

- CALL-ID header
 - To help identifying univocally the registration transaction
- Cseq header
 - Has the purpose of mapping correctly responses to requests
- Contact header
 - Specifies who is to be contacted to deliver responses
- In this case, the message body is empty, thus we have
 - Content-Length: 0

anna@pippo.lavoro.it

registrar

```
REGISTER sip:registrar.lavoro.it SIP/2.0
Via: SIP/2.0/UDP pippo.lavoro.it; branch = h739fhry
Max-Forwards: 70
From: sip:anna@pippo.lavoro.it; tag = 123456
To: sip:anna@pippo.lavoro.it
CALL-ID: 123456@pippo.lavoro.it
CSeq: 1 REGISTER
Contact: sip:anna@pippo.lavoro.it
Expires: 7200
Content-Length: 0
```

Registration example

- The figure plots a possible response to the registration request

anna@pippo.lavoro.it

registrar

```
REGISTER sip:registrar.lavoro.it SIP/2.0
Via: SIP/2.0/UDP pippo.lavoro.it; branch = h739fhry
Max-Forwards: 70
From: sip:anna@lavoro.it; tag = 123456
To: sip:anna@lavoro.it
CALL-ID: 123456@pippo.lavoro.it
CSeq: 1 REGISTER
Contact: sip:anna@pippo.lavoro.it
Expires: 7200
Content-Length: 0
```

```
SIP/2.0 200 OK
VIA: SIP/2.0/UDP pippo.lavoro.it; branch = h739fhry
From: sip:anna@lavoro.it, tag = 123456
To: sip:anna@lavoro.it
CALL-ID: 123456@pippo.lavoro.it
CSeq: 1 REGISTER
Contact: sip:anna@pippo.lavoro.it
Expires: 3600
Content-length: 0
```

INVITE

- This example shows a direct call, thus the complete address of the destination host must be specified
- In case of proxy servers, the host indication can be omitted as it can be solved automatically by the proxy
- The nicks *annie* e *luke* are the “display names”, they are optional

anna@pippo.lavoro.it

luca@pluto.lavoro.it

```
INVITE: sip:luca@pluto.lavoro.it SIP/2.0
VIA: SIP/2.0/UDP pippo.lavoro.it; branch = 34f65g
Max-Forwards: 70
From: annie<sip:anna@lavoro.it>; tag = 222333
Contact: sip:anna@pippo.lavoro.it
To: luke<sip:luca@pluto.lavoro.it>
Call-ID: 123456@pippo.lavoro.it
CSeq: 1 INVITE
Subject: shell we go to the restaurant tonight?
Content-length: xxx
Content-type: application/sdp
Content-disposition: session
```

Response to INVITE

- The triplet
 - **(From, To, Call-ID)** is the “dialog ID” which identifies a transaction between two remote user terminals
 - At this point of the signaling transaction, the dialog is established but the call is not set up; the dialog is in the “early” status
 - The dialog becomes “confirmed” when the call is set up

anna@pippo.lavoro.it

luca@pluto.lavoro.it

```
SIP/2.0 180 RINGING
Via: SIP/2.0/UDP pippo.lavoro.it; branch = 34f65g
From: annie<sip:anna@lavoro.it>; tag = 222333
To: luke<sip:luca@pluto.lavoro.it>; tag = 111000
Contact: sip:luca@pluto.lavoro.it
Call-ID: 123456@pippo.lavoro.it
CSeq: 1 INVITE
Content-Length: 0
```

Confirmation to INVITE

- With the OK message the call is established and the dialog is “confirmed”

anna@pippo.lavoro.it

luca@pluto.lavoro.it

```
SIP/2.0 200 OK
VIA: SIP/2.0/UDP pippo.lavoro.it; branch = 34f65g
From: annie<sip:anna@lavoro.it>; tag = 222333
To: luke<sip:luca@pluto.lavoro.it>; tag = 111000
Contact: sip:luca@pluto.lavoro.it
Call-ID: 123456@pippo.lavoro.it
CSeq: 1 INVITE
Subject: cosa fai stasera
Content-Length: xxx
Content-Type: application/sdp
Content-Disposition: session
message body

ACK: sip:luca@pluto.lavoro.it SIP/2.0
VIA: SIP/2.0/UDP/pluto.lavoro.it; branch = 34f65g
Max-Forwards: 70
From: annie<sip:anna@lavoro.it>; tag = 222333
To: luke<sip:luca@pluto.lavoro.it>; tag = 111000
Call-ID: 123456@pippo.lavoro.it
CSeq: 1 ACK
Content length 0
```

Tear down

anna@pippo.lavoro.it

luca@pluto.lavoro.it

BYE: sip:luca@pluto.lavoro.it SIP/2.0

Proxy server

- Proxy servers route SIP messages to the proper destinations
- More than one proxy can be involved in the setup of a connection
- For example, the setup of a SIP call may involve two proxies: the local proxy of the calling user and the local proxy of the called user

Example (proxy)

BOSS<sip:manager@pc1.home.net>

sip:server.work.com

daniel<sip:collins@station1.work.com>

```
INVITE sip:collins@work.com SIP/2.0
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7890
Max-Forwards: 70
From: boss<sip:manager@home.net>;tag=ab12
Contact: boss<sip:manager@pc1.home.net>
To: daniel<sip:collins@work.com>
Call-ID: 123456@pc1.home.net
CSeq: 1 INVITE
```

```
INVITE sip:collins@work.com SIP/2.0
Via: SIP 2/0/UDP server.work.com; branch z9hG4bKxyz1
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7890
Record-route: <sip:server.work.com;lr>
Max-Forwards: 69
From: boss<sip:manager@home.net>;tag=ab12
Contact: boss<sip:manager@pc1.home.net>
To: daniel<sip:collins@work.com>
Call-ID: 123456@pc1.home.net
CSeq: 1 INVITE
```

```
SIP/2.0 100 Trying
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7890
From: boss<sip:manager@home.net>;tag=ab12
To: daniel<sip:collins@work.com>
Call-ID: 123456@pc1.home.net
CSeq: 1 INVITE
```

```
SIP/2.0 200 OK
Via: SIP 2/0/UDP server.work.com; branch z9hG4bKxyz1
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7890
Record-route: <sip:server.work.com;lr>
From: boss<sip:manager@home.net>; tag=ab12
To: daniel<sip:collins@work.com>; tag=xy45
Call-ID: 123456@pc1.home.net
CSeq: 1 INVITE
Contact: sip:collins@station1.work.com
```

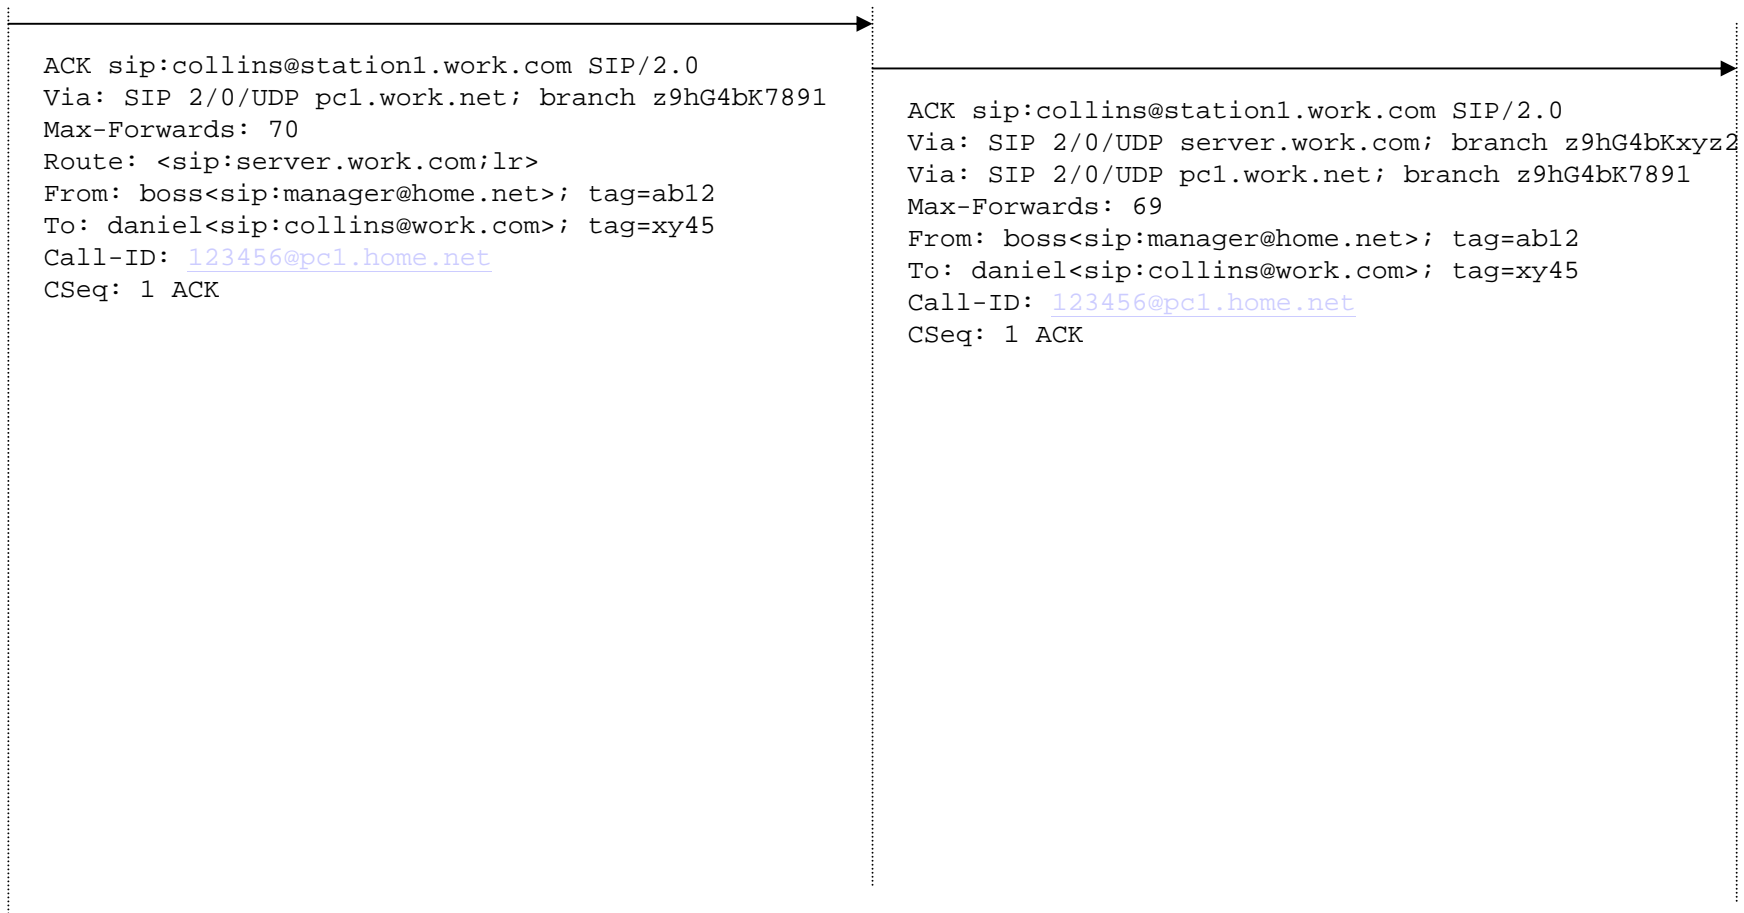

```
SIP/2.0 200 OK
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7890
Record-route: <sip:server.work.com;lr>
From: boss<sip:manager@home.net>; tag=ab12
To: daniel<sip:collins@work.com>; tag=xy45
Call-ID: 123456@pc1.home.net
CSeq: 1 INVITE
Contact: sip:collins@station1.work.com
```

Example (proxy)

BOSS<sip:manager@pc1.home.net>

sip:server.work.com

daniel<sip:collins@station1.work.com>

```
ACK sip:collins@station1.work.com SIP/2.0
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7891
Max-Forwards: 70
Route: <sip:server.work.com;lr>
From: boss<sip:manager@home.net>; tag=ab12
To: daniel<sip:collins@work.com>; tag=xy45
Call-ID: 123456@pc1.home.net
CSeq: 1 ACK
```

```
ACK sip:collins@station1.work.com SIP/2.0
Via: SIP 2/0/UDP server.work.com; branch z9hG4bKxyz2
Via: SIP 2/0/UDP pc1.work.net; branch z9hG4bK7891
Max-Forwards: 69
From: boss<sip:manager@home.net>; tag=ab12
To: daniel<sip:collins@work.com>; tag=xy45
Call-ID: 123456@pc1.home.net
CSeq: 1 ACK
```

Comments

- The Via header is important when proxies are involved in signaling
- Each SIP device touched by a SIP message adds a Via header carrying its address
- In this way, the path of SIP devices crossed by a message is explicitly written in the message header
- It is easy to detect SIP routing loops
- Moreover, it is easy to force response messages to follow in the reverse direction the path followed by request messages

Comments

- In the backward path of responses, Via header are stripped from the message at each SIP hop
- The function of the branch parameter is to identify univocally the signalling transaction at each SIP entity crossed by messages
- A stateful proxy must be always in the path followed by all requests and all responses
- The Via header is not enough, because its scope is limited to one request-response interaction
- This is why also the record-route header is used
